### 26 ABSTRACT

- 27 Substituted phenylamine antioxidants (SPAs) are used in Canadian industrial processes. SPAs,
- 28 specifically N-phenyl-1-naphthylamine (PNA), have received very little attention despite their
- 29 current use in Canada and their expected aquatic and environmental releases. There is a research
- 30 gap regarding the effects of PNA in wildlife; therefore, *Chelydra serpentina* (common snapping
- turtle) was studied due to its importance as an environmental indicator species. A chronic
- experiment was performed using PNA spiked food (0 to 3,446  $\mu$ g/g) to determine its toxicity to
- 33 juvenile *C. serpentina*. A significant increase in *cyp1a* mRNA level was observed in the liver of
- turtles exposed to 3,446 ng/g PNA, suggesting that phase I detoxification is activated in the
- 35 exposed animals. Additionally, a significant decrease in *cyp2b* transcript level was observed at
- the two lowest PNA doses, likely indicating another metabolic alteration for PNA. This study
- helped determine the molecular effects associated with a PNA exposure in reptiles.
- **Keywords:** Turtle, toxicity, N-phenyl-1-naphthylamine, metabolism, cytochrome P450.

## **39 INTRODUCTION**

- 40 Substituted phenylamine antioxidants (SPAs) have been used in a variety of lubricants, dyes,
- 41 dispersants, and adhesives to protect the product from oxidation. One SPA, N-phenyl-
- 42 naphthylamine (PNA), is mainly used as an antioxidant in rubber manufacturing and lubricating
- 43 oils (Wang et al., 1984). PNA is composed of a naphthalene base with a phenyl group connected
- 44 by an amine group and is considered lipophilic, as its  $\log K_{ow}$  is 4.2, and thus it is expected to be

45 slightly bioaccumulative with a bioconcentration factor (BCF) between 50 and 500 (Ozeki &

- 46 Tejima, 1979). Using a fugacity modeling approach (McKay, 1991), we estimated that once
- 47 PNA is released into the environment, its distribution is predicted to be the following: 36.3% in
- soil, 33.9% in sediment, 28.9% in water, and 0.016 % in air, suspended sediment, and biota.
- PNA has been measured in sediment and wastewater at concentrations up to 5 and 7  $\mu$ g/g, respectively (Jungclaus et al., 1978; Lopez-Avila & Hites, 1980). More recently, PNA has be
- respectively (Jungclaus et al., 1978; Lopez-Avila & Hites, 1980). More recently, PNA has been
  measured in biosolids from a wastewater treatment Plant (Hamilton, ON, Canada) at a
- 52 concentration of 65 ng/g (Balakrishnan et al., 2016); however, environmental concentration data
- are limited and outdated. As PNA is currently used in industrial processes in open systems and is
- 54 potentially bioaccumulative and persistent in the environment, it can be considered as a
- 55 contaminant of emerging concern. PNA was evaluated as part of the Government of Canada's
- 56 Chemicals Management Plan, whose purpose is to determine the hazard and risk of chemicals
- 57 currently used in commerce in Canada. PNA was evaluated as little is known about the
- environmental exposure, environmental fate, or toxicity of PNA, thus this project was to
  determine the toxicity to wildlife.
- 60 Despite large knowledge gaps of the toxicological significance of PNA, few studies have
- assessed the effects of this chemical in vertebrates. The majority of the studies on the toxicity of
- 62 PNA used mammalian models, and the few data that exist on aquatic vertebrates were acute
- exposures. The  $EC_{50}$  for cell proliferation was determined to be 2 mg/L for *Tetrahymena*
- 64 *pyriformis* (ciliate) exposed to PNA for 48 h (Epstein et al., 1967). The LC<sub>50</sub> was in the range of
- 65 0.44-0.74 mg/L for *Oncorhynchus mykiss* (rainbow trout) and 0.57-0.82 mg/L for *Lepomis*
- 66 *macrochirus* (bluegill). More recently, Prosser et al. (2017) determined that the  $LC_{50}$  in
- 67 *Pimephales promelas* (fathead minnow) was 74  $\mu$ g/L and the EC<sub>50</sub> for deformities was 95  $\mu$ g/L.
- The LC<sub>50</sub> and LC<sub>100</sub> of PNA for *Xenopus laevis* (African clawed frog) were reported to be 2.3
- 69 mg/L and 5 mg/L in *Lithobates pipiens* (Northern leopard frog) (Greenhouse, 1976, 1977).
- Furthermore, development of *L. pipiens* exposed to 20 and 200 mg/L PNA was halted at
- Shumway stage 20, in which death resulted afterwards in 100% of animals (Greenhouse 1976;
- 72 Shumway, 1940). Eye malformations and stunted growth were induced in larval *X. laevis*
- exposed to >5.2 mg/L PNA, whereas death occurred when treated with concentrations at, or
- <sup>74</sup> above 6 mg/L (Greenhouse, 1976). All these studies were based upon aqueous exposures, but
- since PNA is potentially bioaccumulative, dietary exposures may be important. Altogether, these
   studies suggest that at high exposures of PNA may be a hazard to wildlife, but there is a lack of
- data on the molecular mechanism of PNA toxicity, most specifically in reptiles.
- 78 The goal of this study was to determine if a chronic exposure of PNA in diet to juvenile
- 79 *Chelydra serpentina* (snapping turtle) would lead to bioaccumulation and alteration of normal
- physiological functions, such as detoxification, development, and reproduction. It was
- 81 hypothesized that PNA will be slightly accumulative to turtles and would alter the expression of
- a subset of genes related to detoxification and endocrine pathways.

# 84 METHODS & MATERIALS

- 85 Turtle eggs were collected in June 2014, southwest of Long Point Provincial Park (ON, CA), a
- site with few local and known sources of contamination. Eggs were incubated at the Canada
- 87 Centre for Inland Waters (CCIW at Environment and Climate Change Canada (ECCC),
- 88 Burlington, ON, CA) until hatched. Collection and housing were performed as described in
- 89 Colson et al. (*under review*). The animal care protocol was approved by the Animal Care
- 90 Committee of Queen's University (Kingston, ON, CA) and followed the guidelines of the
- 91 Canadian Council of Animal Care.

Trout chow pellets (Martin PROFISHENT<sup>™</sup>) were treated with PNA (98%; CAS 90-30-92 2; TCI Chemicals, Portland, OR, USA) using a rotary evaporator (Buchi Vacobox B-177; Taylor 93 Scientific St. Louis, MO, USA) at CCIW (ECCC). A stock solution of 0.1 mg/L PNA was made 94 95 by dissolving PNA into acetone (99.7% pure, distilled in glass; Caledon Laboratories Ltd., Georgetown, ON). Trout chow was dosed in two batches and placed into the bottom flask with 96 97 the appropriate volume of stock solution and topped with acetone such that the total volume of 98 the solution was 100 mL. The control food was treated the same way; however, only 100 mL of 99 unadulterated acetone was added to the flask in place of the PNA solution. After mixing the contaminated pellets they were under a fumehood for 30 min, while being incubated in a 100 waterbath at approximately 30 °C. The pressure of the rotary evaporator was initially set at 556 101 mbar, and  $\Delta H$  was set to 1.0, although the pressure was increased near the end of the 102 103 evaporation. The food mixture was run for about 1 h, occasionally shaken by hand during this 104 time. The treated trout chow was placed on aluminum foil and let sit in a fume hood for 24 h, stored in plastic containers, and kept frozen at -20 °C. 105 Turtle hatchlings (n = 70) were housed in 2.2-L plastic containers with roughly 250 mL 106 107 of water to allow turtles to submerge, while still allowing easy access for the turtles to breathe. Turtles (n = 14 per treatment) were chronically-exposed to a range of nominal PNA 108 concentrations (0, 0.01, 0.1, 1.0, and 10  $\mu$ g/g) for 81 days. Each hatchling was fed 5 pellets twice 109 a week for the duration of the experiment. 110 Turtle hatchlings were sacrificed on day 81 of the exposure by decapitation (as per 111 Colson et al. under review). Brain, liver, and GMC (gonad-mesonephros complex) were 112 collected, weighed, and immediately placed on dry ice and stored at -80 °C until further use. In 113 addition, the whole body was weighed and carapace length was measured for morphometric 114 analyses. Somatic indices were calculated for each collected tissue. Livers were further tested to 115 measure PNA concentrations and mRNA levels. 116 The extraction and measurement of PNA concentration in turtle liver were performed by 117 liquid chromatography-tandem mass spectrometry (LC-MS/MS; (Balakrishnan et al., 2016). 118 Tissue samples (0.1 g dry weight) were spiked using a SPA solution in MeOH and then 119 evaporated and extracted in 10 mL acetonitrile using ultrasound assisted extraction. Lipids were 120 removed by gel permeation chromatography in columns packed with 30 cm of BioBeads (200-121 400 mesh; BioRad) that were prepared in 50:50 DCM:Hexane (v/v). Extracts were filtered 122 through Allihn funnels through a 10 cm bed of Celite 545 (Fisher Scientific) on a 1.2 µm 123 Whatman GFC filter (VWR Scientific). Nitrogen was used to dry the filtrate to 1 mL. The 124 extracts were then eluted using 50:50 DCM:Hexane (v/v) in a packed GPC column. Nitrogen 125 was again used to evaporate the DCM:hexane eluate to dryness, after which it was reconstituted 126 in 1 mL MeOH. Samples were analyzed using a XEVO tandem LC triple quadrupole mass 127 spectrometer (Waters, Milford USA) equipped with a Z-Spray electrospray ionization source and 128 129 operated in the positive-ion mode. MassLynx software (v. 4.1) was utilized for both data acquisition and processing. Multiple reaction monitoring and selected ion reaction modes were 130 used. Aliquots were injected into an UPLC system (Waters, Milford, MA) with a 2.6 µm-pore 131 size Kinetex C18 column (2.1 mm x 100 mm; Phenomenex, USA). All PNA concentrations were 132 normalized against the <sup>2</sup>H-labeled 1,4-benzene-d<sub>4</sub>-diamine internal standard (internal standard 133 quantification). Total RNA was extracted using TRIzol solution followed by a lithium chloride 134 treatment. DNA contamination was removed by performing DNase I treatment following the 135 manufacturer's protocol (Promega RQ1 RNase-Free DNase kit; Fisher Scientific, Ottawa, ON, 136 CA). Random primers were used to convert RNA to 1 µg cDNA using and following Promega 137

- 138 GoScript<sup>™</sup> Reverse Transcription System Kit protocol (Madison, WI, USA). The thermocycle
- 139 program included an annealing temperature of 25  $^{\circ}$ C for 5 min, extending temperature of 42  $^{\circ}$ C
- 140 for 60 min, and 15 min at 70 °C to inactivate the reverse transcriptase. Samples were kept at -20
- <sup>141</sup> °C until further use. Eight detoxification-related genes (*i.e., ahr, arnt, cyp1a, cyp2b5, cat, gpx1*,
- sod1, and hsp70) were analyzed. Additionally, a subset of thyroid hormone-related genes (dio2,
- 143 dio3, thra, and thr $\beta$ ) and sex steroid-related genes (ar and esrl) were analyzed to determine
- potential for endocrine disruption. Primers were either obtained from Colson et al. (*under*
- 145 *review*) or Rhen et al. (2007) (Table 1).
- 147 **Table 1.** Primer design and conditions for genes involved in detoxification, thyroid hormone,
- 148 and sex steroid pathways in *C. serpentina*. F: forward primer, R: reverse primer. *odc*: ornithine

Gene expression analysis was measured on an Agilent Mx3005P Real-Time PCR (qPCR; Agilent Technologies, Inc., Santa Clara, CA, USA) using the Promega GoTaq Bryt® Green qPCR Master Mix (2X; Fisher Scientific). For each qPCR assay, a negative template control and a negative reverse transcriptase control were included to ensure no contamination. A standard curve was prepared through serial dilution (1:4) starting at 50 ng. All samples, controls, and the

standard curves were run in duplicate. Efficiencies ranged between 83-122%, and coefficients of

- determination  $(R^2)$  were above 0.983. Gene expression was normalized to the quantified relative
- 163 expression of *odc*. Gene expression changes were reported as fold changes relative to the164 controls.
- 165 Statistical analysis of gene expression was done using Prism GraphPad Prism 6
- 166 (GraphPad Software Inc, San Diego, CA, USA). Observations that were outside 1.5x
- 167 interquartile range (IQR) were removed as outliers prior to analysis and data were transformed
- 168 (log<sub>10</sub> or square root) if not normally distributed. Comparisons of gene expression analysis
- among treatments were performed using a one-way ANOVA followed by Tukey's HSD test.
- Treatments were considered significantly different if p-values were equal to, or below 0.05.

#### 172 **RESULTS & DISCUSSION**

- 173 PNA concentrations were measured in food pellets to determine the actual dose given to *C*.
- serpentina. Mean concentrations in liver for each treatment were 0.02, 0.54, 0.05, 0.55, and 7.62
- $\mu g/g$ , dry weight when exposed to pellets of 0, 4, 38, 964, and 3,446  $\mu g/g$ , dry weight PNA,
- respectively (Fig 1). A significant increase was observed in PNA concentrations in liver ( $R^2$ :
- 177 0.78; Fig 1). Livers from the two highest treatments accumulated significantly more PNA than
- the control (0.55 and 7.62  $\mu$ g/g compared to 0.02  $\mu$ g/g, respectively). In addition, the
- 179 bioaccumulation factors in liver (liver concentration/concentration in food) calculated for the two
- highest treatments were 0.006 and 0.0023 in liver, respectively.
- **Fig 1.** PNA accumulation in the *C. serpentina* liver exposed to varying concentrations (0 3,446)
- 183  $\mu g/g$  PNA, dw) after 81 d. Data is presented as mean (n = 7-9) ± SD. A significant sigmoidal
- increase was noted p < 0.05 and denoted by an asterisk (\*) after a one-way ANOVA.
- 185

186

187 A range of morphometric measurements were taken at experiment completion to assess if PNA altered growth in juvenile C. serpentina. Body mass ranged between 9.2 and 19.2 g, while 188 carapace length ranged from 3.2 to 4.1 cm across treatments, with averages of 13.6 g and 3.7 cm, 189 190 respectively. The gonadosomatic index (GSI) ranged from 0.07 and 0.56 with an average of 0.28. The mean GSI was significantly larger in the highest PNA treatment  $(3,446 \,\mu\text{g/g} \,\text{PNA})$  when 191 compared to that of controls which suggests that PNA exposure can increase gonadal mass. 192 193 Mahboob and Sheri (2002) have determined that the GSI is a good indicator of gonadal 194 enzymatic activity. However, given the lack of research on PNA or related SPAs, no other studies have reported any change in GSI or gonad mass so far. Therefore, the present study 195 196 suggests that PNA can increase gonadal growth; however, due to the lack of expression changes in ar or esr1 mRNA levels, the observed gonadal growth was unlikely mediated through 197

198 differential androgen- or estrogen-receptor mRNA expression. Further research would be

required to investigate this increase in gonadal mass. No other significant differences were foundfor any other morphometric endpoints.

- Fourteen genes were targeted to assess detoxification, oxidative stress-, thyroid hormone-, and reproductive-related pathways. A significant 2.7-fold increase (p = 0.0003) in *cyp1a* mRNA level was observed after exposure to 3,446 µg/g PNA (Fig. 2a). This may indicate that
- 204 PNA can be detoxified through phase I metabolism. CYP1A is the enzyme responsible for the
- addition of hydroxyl groups during xenobiotic metabolism. This increase in *cyp1a* expression in
- 206 *C. serpentina* suggests that PNA may be metabolized through hydroxylation in the turtle liver.
- 207 For example, hydroxylated metabolites of PNA were detected in rat microsomes following in
- vitro exposure (Xuanxian et al., 1992). Taken together, the increase in *cyp1a* mRNA level
- 209 measured in this study and the susceptibility of PNA to be metabolized into hydroxylated
- 210 metabolites, suggest that PNA is likely metabolized in the liver via the CYP1A pathway.
- Fig 2. Cytochrome P450 gene expression in *C. serpentina* liver after exposure to 0 (gray box)
- and 4 3,446 (black boxes)  $\mu$ g/g PNA. Data are presented as mean fold change + SEM.
- Significance (p < 0.05) compared to control is depicted by an asterisk (\*) after a one-way
- ANOVA and Tukey's test. cyp1a = cytochrome P450 1A; cyp2b5 = cytochrome P450 2B5

216

In contrast, significant 0.5- and 0.4-fold decreases (p = 0.0084) were observed in *cvp2b5* 217 transcript level after exposure to 4 and 38  $\mu$ g/g PNA, respectively (Fig. 2b). No other changes in 218 gene expression were observed. Most interestingly, a U-shaped response was observed for 219 cyp2b5 transcript level with initial decreases in cyp2b5 mRNA levels at low doses and then a 220 221 return to control levels at higher doses, which suggests a hormetic response. Hormesis is a doseresponse relationship in which the response resembles a U-shape or an inverted U-shape due to 222 stimulation at low doses but inhibition at high doses (Davis & Svendgaard, 1990). Many 223 underlying mechanisms may be responsible for hormesis, such as an overcompensation to 224 maintain homeostasis at low doses of a toxicant (Calabrese & Baldwin, 2001). For example, 225 exposure to dioxin-like compounds can create a U-shape response at low doses, which coincides 226 227 with the multiple different effects of dioxins, such as cell proliferation, toxicity, and mitosuppression for tumour induction (Andersen & Barton, 1998). Further investigation would 228 229 be needed to validate and explain the inverted U-shaped response measured for cyp2b5 in 230 C. serpentina livers. 231 Despite the alterations observed for the expression of the two *cyp* genes analyzed, no other

changes were noted for any of the phase II detoxification- or oxidative stress- related genes

- investigated. This can be partly explained by the turtle's high tolerance to oxidative stress.
- 234 *C. serpentina* are known to have high basal antioxidant defenses (i.e., CAT, SOD, and GST)

- 235 (Hermes-Lima & Zenteno-Savin, 2002). This high level of antioxidants allows turtles to resist
- long periods of stress, such as hibernation, in which they undergo anoxia (Storey, 1996), in
- which reactive oxygen species are generated during periods of high oxygen tension during
  reoxygenation (Krivoruchko & Storey, 2010).
- This is the first study to determine if PNA is toxic to reptiles, and more specifically, in
- turtles. Overall, our data have shown that PNA accumulates, albeit slightly, in the turtle liver and
- suggests that it can be likely metabolized by P450 enzymes. Further investigation is needed to
- 242 understand the exact detoxification mechanisms of PNA in juvenile turtles. Understanding how
- emerging contaminants, such as PNA, can affect wildlife is imperative to assist environmental
- risk assessment to prevent negative health consequences to wildlife populations.

## 246 ACKNOWLEDGEMENTS

- 247 The authors would like to thank Kyna Intini, Kim McCormack, Kimberly O'Hare and Sara
- 248 Witzke of ECCC for turtle egg collection and Sarah Wallace and Christina Emerton (RMC) for
- their help with exposures, animal care, and sampling. Funding was provided by Ecotoxicology
- and Wildlife Health Division (ECCC) to SdS and Canada Research Chair (CRC) to VSL.
