## 1. INTRODUCTION

During the period 1978-1983 the World Meteorological Organization (WMO) carried out an international intercomparison of conceptual models of snowmelt runoff [WMO, 1982].

The aims of the project were:

- to assemble information on existing models used operationally to estimate snowmelt runoff;
- to compare snowmelt runoff models with regard to their structure, conceptual basis and data needs;
- to evaluate and obtain an insight into their performance and accuracy of estimation, and
- to disseminate the information and results obtained so as to popularize new approaches to forecasting snowmelt runoff and assist countries in the selection and application of models for this purpose.

Ten models submitted by seven countries were included in the project and fitted to six standard data sets submitted by six countries.

Each data set comprises a six-year calibration period and a four year verification period. Graphical and numerical verification criteria were used to analyse the results of the models; the final report is in preparation and will be published by WMO.

The participants of the technical conference held in Norrköping, Sweden on September 26-30, 1983 expressed the opinion that it would be desirable to estimate confidence intervals for the values of the verification criteria in order to determine whether the differences between the criterion values are significant or the result of sampling variations.

At the conference, it was decided that, in addition to the values based on the entire calibration and verification periods and the snowmelt seasons, annual values should be computed as well for the criteria R, NTD, S and NS.

In this report, we used these criteria, which are defined as follows:

- Ratio of the mean error to the mean observed discharge:

$$R = \frac{\sum(y_c - y_o)}{n \bar{y}_o}$$

- One minus ratio of the sum of squares of the daily residuals to the centered sum of squares of the daily observed discharges:

$$NTD = \frac{\sum(y_o - \bar{y}_o)^2 - \sum(y_c - y_o)^2}{\sum(y_o - \bar{y}_o)^2} \text{ for mean daily discharges}$$

- Ratio of the standard deviation of the residuals to the mean observed discharge:

$$S = \frac{\sqrt{\left[ \frac{\Sigma(y_c - y_o)^2}{n} \right]}}{\bar{y}_o}$$

- Coefficient of gain from daily means:

$$NS = \frac{\Sigma(y_o - \bar{y}_{od})^2 - \Sigma(y_c - y_o)^2}{\Sigma(y_o - \bar{y}_{od})^2}$$

In the above equations:  $y_o$  : observed discharge;  $y_c$  : computed discharge;  $n$  : total number of observations;  $\bar{y}_{od}$  : mean daily observed discharge for each day of the year derived from the calibration period.

The models and the basins used in the Intercomparison Project are given in the following table:

BASINS	MODELS	
	MODEL	ABBREVIATION IN THIS REPORT
Durance (France)	UBC	UBC
W3 (U.S.A.)	CEQUEAU	CEQ
Dunajec (Poland)	ERM	ERM
Dischma (Switzerland)	NAM-II	NAM
Illecillewaet (Canada)	TANK	TAN
Kultsjon (Sweden)	HBV	HBV
	SRM	SRM
	SSARR	SSA
	PRMS	PRM
	NWSRFS	NWS
	DAILY MEAN ("Peasant")*	DAY

\* This "model" was not included in the intercomparison project. It consists of the mean daily observed discharge for each day of the year derived from the calibration period.

As a first step the annual values of the criteria defined above were studied. The annual values of the criteria for all basins, periods and seasons are given in Appendices A and B. As an example, Table 1 and Figure 1 give the values of the criterion NTD for the Durance River. The value (-1.000) denotes that the model has not been tested in a given case.

In Figure 1, each asterisk represents the annual value of the criterion for the calibration and verification periods. If the annual value is the same for more than one year, the asterisk is replaced by a digit showing the number of repetitions. The symbol "I" indicates that at least one annual value is outside the range of the scale.

An examination of the tables and graphs indicates that criterion values vary for different years and models. There is an overlap between the range of the annual values of the criteria for different models which indicates that the difference between criterion values may be due to sampling variation and therefore it would be useful to compute confidence intervals. In this connection, it is interesting to note that the dispersion of the criterion values of a given model for different years is an indication of the consistency of its performance.

FIGURE 1. ANNUAL CRITERION VALUES

NTD

COMPLETE YEAR

SNOWMELT SEASON

The verification criteria are complicated functions of the observed and estimated flows and therefore the computation of exact confidence intervals is mathematically intractable. In this report, two different approaches were used to compute approximate confidence intervals.

The first approach is the standard two-way analysis of variance and the second is the Jackknife statistic which is of general applicability.

It must be noted that confidence intervals for the criterion values were also computed using Friedman's (Hollander and Wolfe, 1973) non-parametric two-way analysis of variance method. The results of this computation were less sensitive in discriminating between model performances than both the ordinary Anova and the Jackknife statistic and therefore they are not included.

## 2. ESTIMATION OF CONFIDENCE INTERVALS

### 2.1 Two-way analysis of variance

A two-way analysis of variance can be used to determine the effects of the years and the models on the values  $V_{ij}$  of the verification criterion  $V$  where  $(i)$  represents the year and  $(j)$  represents the model. It must be noted however, that in our case, as is apparent from the graphs of the

previous section, the basic assumptions of the analysis of variance (homoscedasticity, independence and normality of residuals) are not satisfied in most cases. In addition, confidence intervals computed by the standard two-way Anova are based on the pooled standard deviation and therefore cannot take into account the differences in dispersion between models and can only give an indication of the size of the confidence intervals.

Table 2 shows the results of a two-way analysis of variance for the criterion NTD of the annual values of Table 1 and the 95% confidence intervals based on the pooled standard deviation.

Figure 2 shows in graphical form the confidence intervals of Table 2. On this graph, " $\bar{V}$ " represents the arithmetic mean of the annual values of the criterion.

It must be noted that the confidence intervals in the figures are cut-off if the upper or lower limit of the interval is outside the range of the scale. This is indicated by the symbol "I".

Figure 2 shows that the confidence intervals for NTD are very wide for the verification period. This is due to the fact that the pooled standard deviation is influenced strongly by models with high variability of the NTD values.

COMPLETE YEAR

SNOWMELT SEASON

This is a serious limitation of the standard two-way ANOVA approach.

Given that the confidence intervals for NTD are very wide it was considered useful to include the corresponding tables and graphs for the criterion S which has a smaller variability (Table 3, Figure 3).

Based on the confidence intervals already computed, we can determine groups of models which are not significantly different, i.e. the lower NTD values are within the confidence interval of the higher NTD values.

Figure 4 shows groups of models whose NTD values are not significantly different. The figure should be read from the higher to the lower values of NTD. For example, for the calibration period (complete year), the models TANK, NAM-II, UBC and NWSRFS are within the confidence interval of the best model (SSARR). Figure 5 shows the corresponding results for the criterion S.

The above computations were carried out for all basins, criteria, periods and seasons. The results show that the confidence intervals based on the pooled standard deviation are not a reliable guide to model performance and therefore the remaining tables and graphs are not included in this report.

## 2.2 Jackknife statistic

The Jackknife statistic is a refinement of methods of direct assessment of sample variability (Mosteller and Tukey, 1977). This technique is based on the subdivision of the sample in a number of subsamples and the computation of the statistic by omitting each subsample in turn. The statistic thus obtained has a t-distribution and therefore can be used to compute confidence intervals for the values of the verification criteria.

In this connection, it must be noted that the Jackknife statistic is generally valid for independently and identically distributed observations. The use of this statistic in the present context is justified by the lack of autocorrelation of annual flows since the groups used in the computation of the statistic consist of the daily flow for individual years.

The procedure for computing the Jackknifed estimates and the corresponding confidence intervals for the values of the verification criteria consists of the following steps:

- 1) Given the observations:

$$Z_i = (y_{oi} - y_{ci}), i = 1, 2, \dots, n$$

compute the value of the verification criterion  $V_{all} = f(z_1, \dots, z_n)$  for all the data.

- 2) Subdivide the data into  $\ell$  groups where  $\ell$  is the number of years in the calibration or verification period.
- 3) Let  $V_{(j)}$  be the value of the criterion computed from the portion of the sample that omits the  $j$ -th group. Compute the "pseudovalues"

$$V_{*j} = \ell V_{\text{all}} - (\ell-1) V_{(j)}$$

$$j : 1, 2, \dots, \ell$$

- 4) The "Jackknifed" value of  $V$  is

$$V_* = \frac{1}{\ell} (V_{*1} + \dots + V_{*\ell})$$

and

$$\text{Var} (V_*) = \frac{1}{\ell} \text{Var} (V_{*j})$$

$$= \frac{1}{\ell} \left[ \frac{\sum (V_{*j} - V_*)^2}{\ell-1} \right]$$

$$= \frac{1}{\ell} \left[ \frac{\sum V_{*j}^2 - \frac{1}{\ell} (\sum V_{*j})^2}{(\ell-1)} \right]$$

- 5) To form confidence intervals for  $V_*$ , use the t-distribution with  $(l-1)$  degrees of freedom.

Table 4 shows the results for the criterion NTD for the Durance River including the 95% confidence intervals. The tables for all the criteria are shown in Appendix C.

Figure 6 shows in graphical form the confidence intervals of Table 4. The graphs for all the criteria are shown in Appendix D.

It must be noted that the symbol  $V$  in the graphs represents the jackknifed value  $V_*$ .

Figure 7 shows the model groups based on confidence intervals of the criterion NTD calculated with the Jackknife statistic. The model groups for all the criteria are shown in Appendix E.

### 3. CONCLUSIONS

#### A. METHODOLOGY

The following methods were used for computing confidence intervals:

- 1- The method of ordinary ANOVA which is based on the pooled standard deviation and therefore cannot take into account the difference in variances between models.

- 2- Friedman's non-parametric two-way ANOVA based on ranks, which is not sufficiently sensitive in discriminating between models.
- 3- The Jackknife statistic which can take into account the different variabilities of the models but cannot provide non-symmetric confidence intervals which are more realistic in some cases. In addition, the Jackknife is valid only for identically and independently distributed random variables. Consequently, it was necessary to subdivide the data into complete years, which reduced the number of groups used in the computation of the Jackknife statistic. Despite this limitation, it was decided that the Jackknife statistic is to be preferred to the two other methods.

## B. RESULTS

- 1- An examination of the tables and graphs of the verification criteria indicates that there is an overlap between criterion values and consequently it is desirable to estimate confidence intervals.
- 2- The confidence intervals of the criterion values based on the jackknife statistic indicate that the models can be classified into groups within which the performances are not significantly different. In this case, model performance must be evaluated on the basis of factors other than the numerical verification criteria.
